

Trellis Codes

Lecture 12

Vladimir Stojanović

6.973 Communication System Design – Spring 2006
Massachusetts Institute of Technology

Trellis codes

- ❑ Invented by Gottfried Ungerboeck of IBM in 1982
- ❑ [1] G. Ungerboeck "Channel coding with multilevel/phase signals," *IEEE Transactions on Information Theory*, vol. 28, no. 1, pp. 55-67, 1982.
- ❑ [2] G. Ungerboeck "Trellis-coded modulation with redundant signal sets Part II: State of the art," *IEEE Communications Magazine*, vol. 25, no. 2, pp. 12-21, 1987.
- ❑ [3] G. Ungerboeck "Trellis-coded modulation with redundant signal sets Part I: Introduction," *IEEE Communications Magazine*, vol. 25, no. 2, pp. 5-11, 1987.

4-state Ungerboeck Trellis code

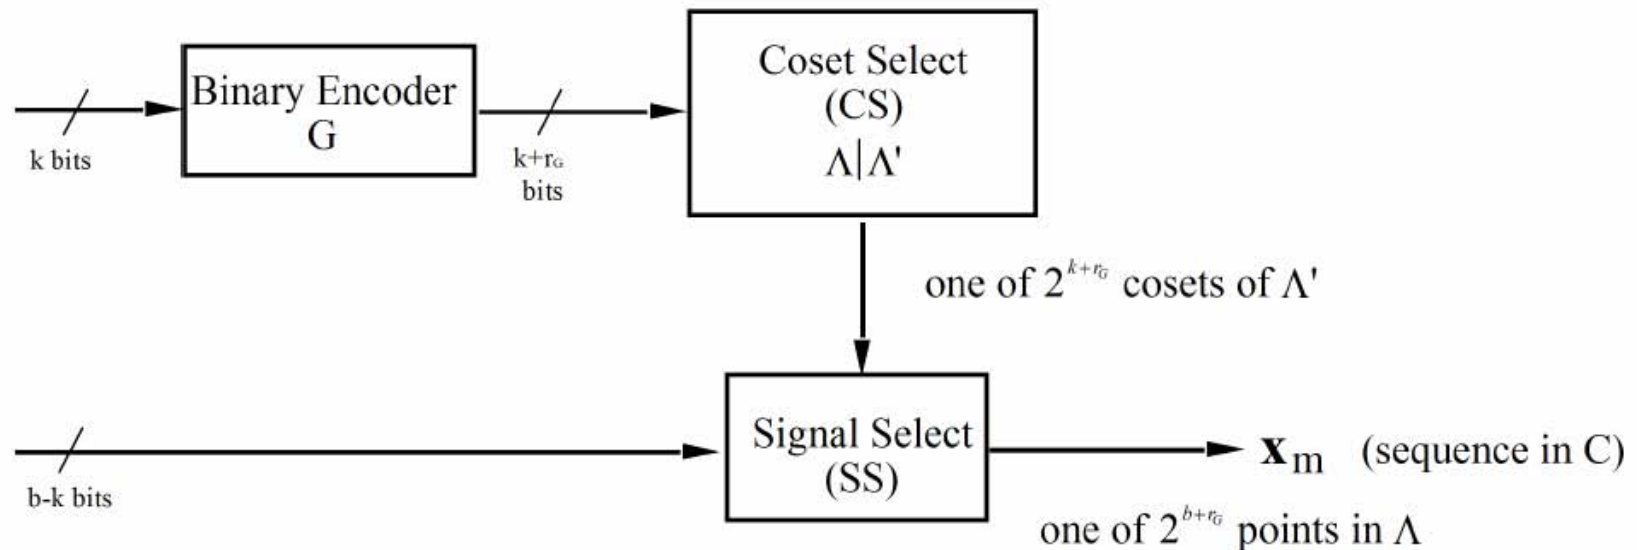

- 1 bit controls the subset (input to conv. encoder)
 - 2 bits choose a point in a subset
- Two minimum distance scenarios
 - Distance between two points in a subset (2 times greater than uncoded 8SQ QAM)
 - When two sequences differ in more than one symbol period
 - Symbol points either chosen from even or odd subsets
 - Within the odds or evens distance the same as 8SQ QAM
 - Diverging at one state and merging at another state forces the squared distance to be doubled
 $d_{8SQ}^2 + d_{8SQ}^2 = 2 d_{8SQ}^2$
- So, this code 3dB better than uncoded 8SQ QAM transmission

Trellis codes – Motivation

- ❑ In multi-level modulations
 - Trellis codes allow code design directly for maximization of Euclidean distance
- ❑ Hamming distance maximizes Euclidean distance only in binary modulation

General coset (subset) encoder

- ❑ x_m – N dimensional vector sequence of points
 - Each N-dimensional symbol chosen from N-dim constellation
 - Sequences of x_m are the codewords $x(D)=\sum_m(x_m D^m)$
- ❑ Signal constellation has 2^{b+rg} signal points in some coset of N-dimensional real lattice Λ
- ❑ Signal constellation contains 2^{k+rg} cosets, each with 2^{b-k} points
- ❑ $rg_bar=rg/N$ – normalized redundancy
- ❑ $kg_bar=k/N$ – informativity of the coset code

Coset partitioning

- ❑ Coset partitioning $\Lambda | \Lambda'$
 - Partition of the lattice Λ into $|\Lambda | \Lambda'|$ (called the “order” of the partition) cosets of a sublattice Λ' such that each point in the original lattice Λ is contained in one, and only one, coset of the sublattice Λ'
- ❑ If the encoder G is
 - Convolutional encoder
 - The set of all possible transmitted sequences $\{x(D)\}$ is a **Trellis Code**
 - Block encoder
 - The set of N -dimensional vectors is a **Lattice Code**
- ❑ Both trellis codes and lattice codes are coset codes

Gain of coset codes

- The fundamental gain always with respect to the uncoded system (\tilde{x})

$$\gamma_f = \frac{\frac{d_{min}^2(\mathbf{x})}{\mathcal{V}_{\mathbf{x}}^{2/N}}}{\frac{d_{min}^2(\tilde{\mathbf{x}})}{\tilde{\mathcal{V}}_{\mathbf{x}}^{2/N}}} = \frac{\frac{d_{min}^2(\mathbf{x})}{2^{2(b+\bar{r}_G)} \mathcal{V}^{2/N}(\Lambda)}}{\frac{d_{min}^2(\tilde{\mathbf{x}})}{2^{2b} \cdot \mathcal{V}^{2/N}(\Lambda)}} = \frac{\frac{d_{min}^2(C)}{2^{2\bar{r}_G} \cdot \mathcal{V}^{2/N}(\Lambda)}}{\frac{1}{1}} = \frac{d_{min}^2(C)}{\mathcal{V}(\Lambda)^{2/N} 2^{2\bar{r}_G}}$$

- Lattice redundancy $\mathcal{V}(\Lambda) = 2^{r_\Lambda} = 2^{N \bar{r}_\Lambda}$

$$\gamma_f = \frac{d_{min}^2(C)}{2^{2(\bar{r}_G + \bar{r}_\Lambda)}} = \frac{d_{min}^2(C)}{2^{2\bar{r}_C}}$$

$$\bar{r}_C = \bar{r}_G + \bar{r}_\Lambda \quad .$$

- Coding gain between 3 and 6dB
- Shaping gain ~ 1.5 dB (fixed by constellation geometry)

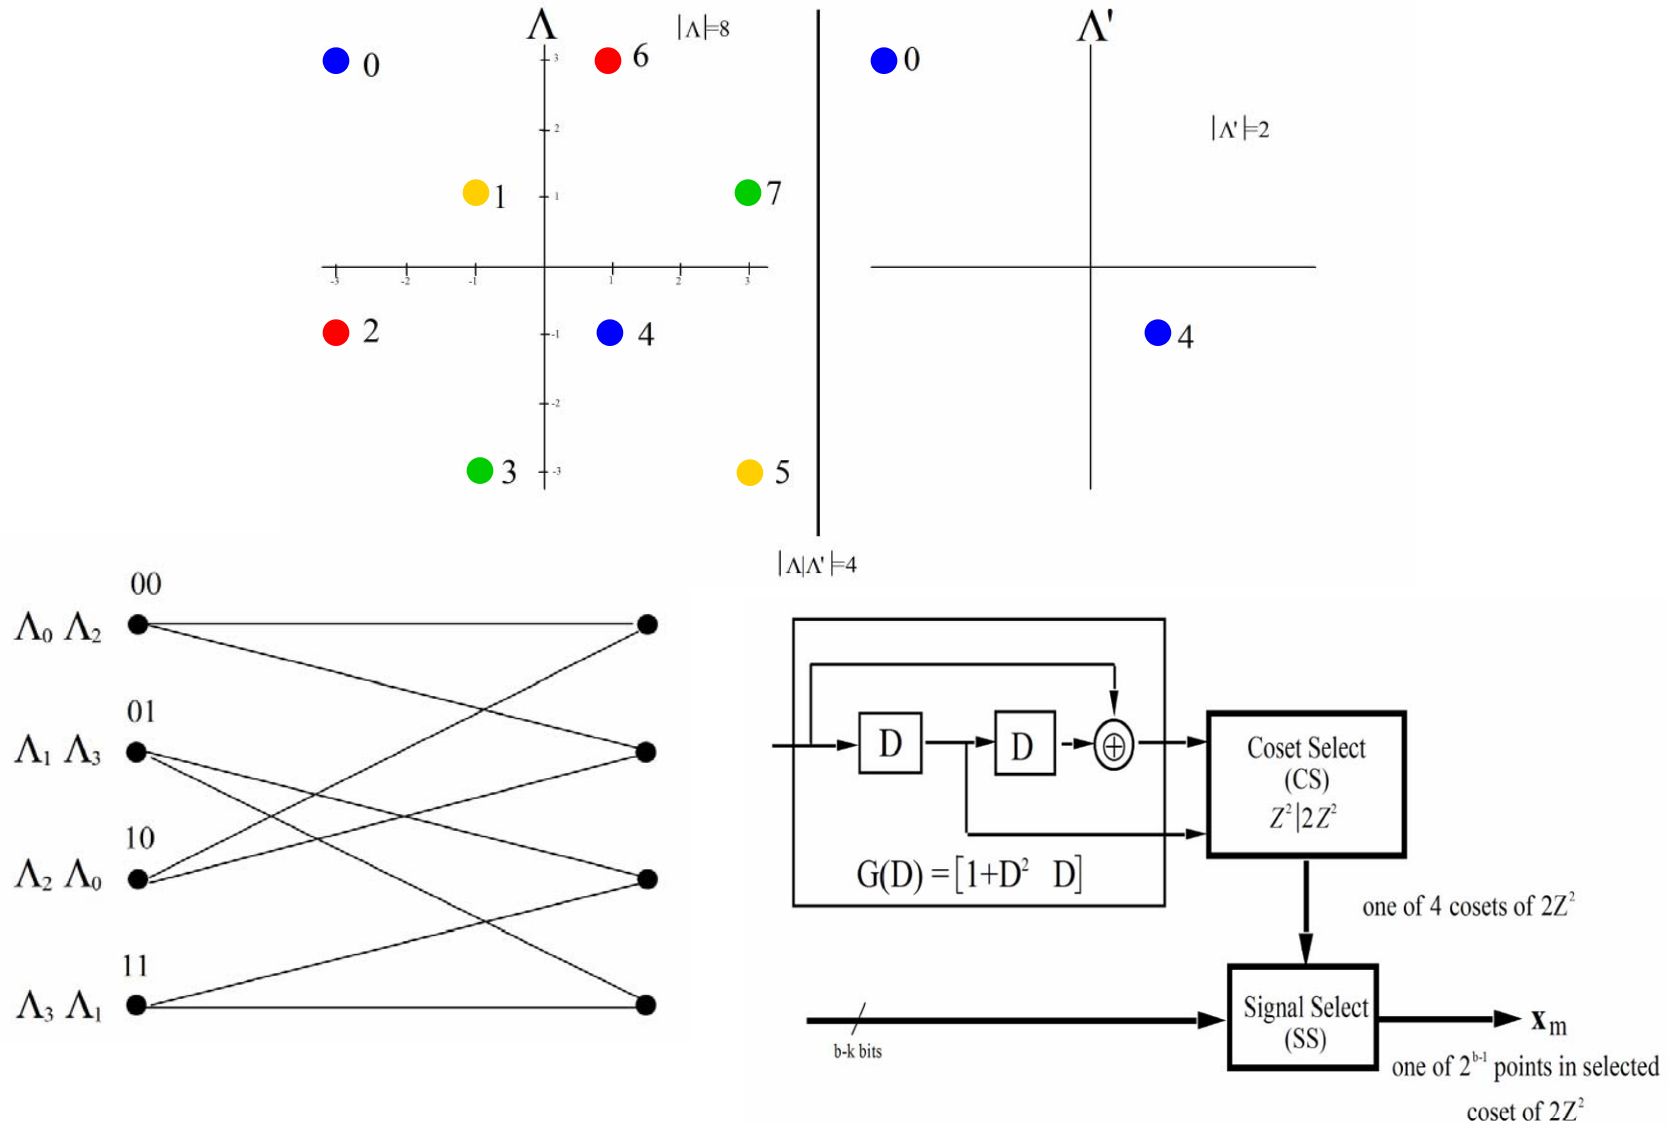

$$\gamma_s = \frac{\mathcal{V}^{2/N}(\Lambda) \cdot 2^{2\bar{r}_G}}{\bar{\mathcal{E}}(\Lambda)} / \frac{1}{(2^{2\bar{b}} - 1)/12} = \frac{2^{2\bar{r}_C}}{12\bar{\mathcal{E}}} (2^{2\bar{b}} - 1)$$

Coset partitioning example (D_2 lattice)

- Ungerboeck rate $\frac{1}{2}$ 3dB trellis code
 - 8AMPM (or 8CR) constellation is a subset of $\Lambda=D_2$ lattice that contains $|\Lambda|=8$ points
 - Average energy per symbol is $E=10$ ($\bar{E}=5$)
 - Sublattice Λ' has a coset Λ_0 with two points $|\Lambda_0|=2$ so that $|\Lambda/\Lambda'|=4$ cosets of Λ' in Λ
 - $\Lambda_0=\{0,4\}$ $\Lambda_1=\{1,5\}$ $\Lambda_2=\{2,6\}$ $\Lambda_3=\{3,7\}$
 - These cosets selected by two bit, rate $\frac{1}{2}$ convolutional encoder output

$$G(D) = [1 + D^2 \quad D]$$

Example, continued

- Min. distance in cosets $d_{\min}(\Lambda') = 2d_{\min}(\Lambda) = 4\sqrt{2}$
- Sequence distance (any two paths that start and terminate in the same pair of states must have a distance that is $d' = \sqrt{16+8+16} \geq 4\sqrt{2}$)
- So, the parallel transition distance is the minimum distance for this code
 - This is still $\sqrt{2}$ better than distance corresponding to no extra bit (or just transmitting uncoded 4QAM)

$$\gamma = \frac{(d_{\min}^2/\mathcal{E}x_p)_{\text{coded}}}{(d_{\min}^2/\mathcal{E}x_p)_{\text{uncoded}}} \quad \gamma = \frac{16 \cdot 2}{\frac{1}{1/2}} = 1.6 = 2 \text{ dB}$$

The fundamental coding gain is (realizing that $\bar{r}_C = \bar{r}_A + \bar{r}_G = 1.5 + .5 = 2$)

$$\gamma_f = \left(\frac{d_{\min}^2}{2^{2\bar{r}_C}} \right) = \frac{32}{2^{2 \cdot 2}} = 2 \text{ (3 dB) .}$$

$$\gamma_s = \frac{2^{2 \cdot 2}}{12 \cdot 5} (2^2 - 1) = \frac{4}{5} = -1 \text{ dB .}$$

Mapping by set partitioning

- Basic partitioning can be extended systematically to larger values of b (i.e. constellation sizes)

Image removed due to copyright restrictions.

- Ungerboeck labeling in two dimensions
 - The LSB v_0 of the encoder output is used to specify which of the first 2 partitions ($B_0, v_0=0$ or $B_1, v_0=1$) contains the selected coset of the sublattice Λ' , and then uses v_1 to specify which of the next level partitions (C_0, C_2, C_1, C_3) contains the selected coset of the sublattice, etc.
 - The remaining bits $v_{k+r}, \dots, v_{b+r-1}$ are used to select points within the coset
- In practice, this mapping is often used for $N=1, 2, 4$ and 8
 - One dimensional partitioning halves PAM constellation into sets of “every other point”, realizing 6dB increase in intra-partition distance for each such halving
 - In 4 and 8 dimensions the distance is 1.5dB and 0.75dB per partition, respectively)

BER improvement

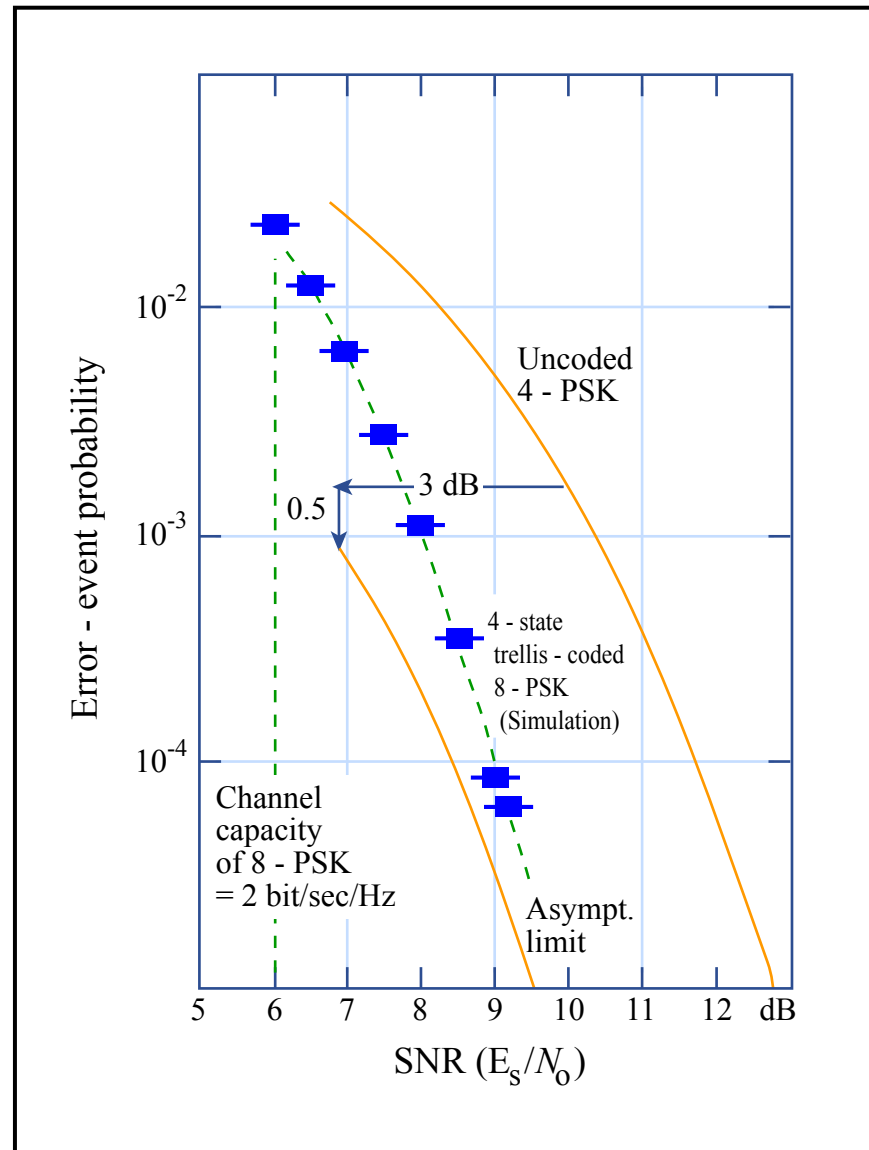

Figure by MIT OpenCourseWare.

6.973 Communication System Design

QAM example

Image removed due to copyright restrictions.

- For m information bits need 2^{m+1} points
 - Extra bit chooses even or odd cosets
 - Coding gain of approx 4dB over uncoded modulation

Trellis for QAM example

Image removed due to copyright restrictions.

- ❑ Error paths with distance $5d_0^2$ from sequence D0-D0-D3-D6
 - All error paths start and re-emerge in one node

Coding gain vs. state

- ❑ Significant gains
 - With as few as 4,8,16 states
 - 3dB (4 states)
 - 4dB (8 states)
 - 5dB (16 states)
 - up to 6dB (128 or more)
- ❑ Doubling of states does not always increase d_{free}
 - Can get big increase in
 - Num. nearest neighbors
 - Num. next-nearest neighbors

Image removed due to copyright restrictions.

Another example

Image removed due to copyright restrictions.

- Rate 2/3 trellis code
 - Increase fundamental gain beyond 3dB (which was the parallel transition distance in the rate $\frac{1}{2}$ code)
 - Need constellation partitioning by one additional level/step to ensure that the parallel transition distance will now be 6dB

Min. distance

- Now, min distance occurs between two longer length sequences through the trellis, instead of between parallel transitions

Images removed due to copyright restrictions.

One-dimensional TCM

- Up to 6dB of fundamental gain $\gamma_f \leq 16/(2^{2 \cdot 1}) = 6$ dB
 - Only need to partition twice $\Lambda' = \Lambda_{(2)}$ to realize min separation between any two parallel transitions that is 6dB higher than uncoded PAM
 - The partition chain for the one-dimensional trellis codes is, with $\Lambda = Z$, $Z|2Z|4Z$, with corresponding min distances between points $d_{\min}(Z)=1$, $d_{\min}(2Z)=2$, $d_{\min}(4Z)=4$, and $r_G=1$
 - The parallel separation is never more than $d^2=16$
 - $G(D)$ must then be a rate $\frac{1}{2}$ code

Two dimensional codes

- Use 3-level partitioning so that $\Lambda' = \Lambda_{(3)}$
 - To realize min separation between any two parallel transitions that is 6dB higher than uncoded two-dimensional QAM
 - The partition chain is with $\Lambda = Z^2, Z^2|D_2|2Z^2|2D_2$
 - Corresponding min distance $d_{\min}(Z^2) = 1, d_{\min}(D_2) = \sqrt{2}, d_{\min}(2Z^2) = 2, d_{\min}(2D_2) = 2\sqrt{2}$ and $r_G = 1$
 - $r_G = 1$ implies doubling of the two-dimensional constellation size $|\Lambda|$ with respect to uncoded transmission. the maximum fundamental gain is limited to $\gamma_f \leq 8/2 = 6\text{dB}$
